

ISMACONNECT Mobile + PWA Testing Plan

Soft-launch checklist for mobile-first QA before marketing starts ? May 12, 2026

Purpose

- Catch mobile and PWA breakpoints before new traffic arrives.
- Verify that first-time phone users can browse, message, save, post, and return without confusion.
- Treat ride share, rentals, services, and worker-logistics flows as the highest-priority launch paths.

What changed in the latest mobile/PWA pass

- Bottom navigation now keeps the correct tab active across grouped routes like categories, listing detail, dashboard flows, settings, and notifications.
- Unread badges now surface in the mobile nav for chat and listing-side activity.
- Settings now includes a real Install ISMACONNECT card so testers can install the app or follow iPhone Add to Home Screen steps without guessing.
- The app shell now reserves safer bottom space for the fixed mobile nav and home-indicator area.

Device matrix

Device / browser	Install state	Must-pass focus
iPhone + Safari	Browser + Add to Home Screen	Install steps, launch icon, fixed-nav overlap, maps, posting, messages
iPhone installed PWA	Standalone app	Cold launch, warm launch, update behavior, push prompt path, cached pages
Android + Chrome	Browser + Install prompt	Install prompt, push notifications, route-group nav, posting flow, map view
Android installed PWA	Standalone app	Resume after close, update behavior, saved-search alerts, message badges
Desktop Chrome / Edge	Browser	Regression sanity for browse, posting, storefronts, settings, and messaging

Critical mobile/PWA tests

1. Install + launch

- Open the site in Safari on iPhone and confirm the Install card in Settings is understandable and accurate.
- Install from iPhone (Add to Home Screen) and Android (prompt/button when available).
- Launch from the home screen and confirm branding, icon, theme color, and session persistence look correct.
- Close and reopen the app twice to confirm it resumes cleanly without broken cached pages.

2. Bottom-nav and shell behavior

- Search should stay active on home, browse, category pages, and listing detail.
- Chat should stay active inside message threads and unread badges should clear after opening messages.
- Listings should stay active on dashboard, settings, account, notifications, and listing-edit screens.
- No primary action, button, or footer content should be hidden behind the fixed mobile nav or phone home indicator.

3. Browse, filters, and maps

- Search by keyword, category, subcategory, and schedule filters on mobile.
- Switch between list and map where available and confirm map pins remain visible when the result list is narrowed by area.
- Open a listing from browse, back out, and confirm filters are preserved.
- Test at least one ride-share map and one rental/services map after install, not just in browser mode.

4. Posting flows

- Create one Offer and one Need from a phone.
- Check that the title placeholder adapts correctly to category and subcategory.
- Verify address, map privacy, pricing type, schedule fields, and photo upload behavior on a real phone keyboard.
- Edit a listing after publish and confirm changes appear in browse, dashboard, and storefront surfaces.

5. Messaging, alerts, and return visits

- Send a message from one account to another and confirm unread badges appear in header/nav.
- Create a saved search, trigger a matching listing, and confirm the alert shows in app surfaces.
- Enable browser notifications on Android or installed PWA where supported and test one message notification end to end.
- Open a notification tap target and confirm it lands on the correct thread or page.

6. Offline and update handling

- Open several pages, switch the phone offline, and confirm cached navigation still works where expected.
- Try posting or messaging while offline and confirm failure states are clear, not silent.
- After a new deploy, confirm the updated app shell replaces the old one without trapping the user on stale pages.
- Verify the offline banner and update prompt are understandable and not visually broken on mobile.

Launch-day acceptance gates

- A first-time phone user can install or at least understand how to install the app.
- A signed-in user can browse, save, message, and post without getting stuck or losing context.
- Maps, posting, and messaging all work in both browser mode and installed-PWA mode.
- No major page is obscured by the fixed nav, safe-area inset, or sticky banners.
- Unread message and activity cues are visible enough to bring people back.

Bug logging format

Field	What to capture
Page / flow	Exact URL or path, plus whether the issue happened in browser mode or installed PWA mode
Device	Phone model, iOS/Android version, browser, and whether the app was installed
Severity	Blocker, High, Medium, or Low
Expected vs actual	One sentence each so the fix target is obvious
Media	Screenshot or screen recording whenever possible

Severity guide

Severity	Definition
Blocker	Stops posting, messaging, sign-in, install, or browsing from working at all. Fix before marketing.
High	Core flow works but looks broken, loses data, hides actions, or confuses first-time users. Fix before serious traffic.
Medium	Rough edge or layout issue that does not stop the task but makes the product feel less polished.
Low	Nice-to-have cleanup that can wait until after soft launch if needed.

Founder scorecard to watch during testing

- Response rate on new ride-share, rental, and service posts.
- Time to first reply for Need posts.
- Saved searches created and alerts opened.
- Unread message volume versus messages actually answered.
- Any page where mobile users hesitate, abandon, or immediately bounce.

Recommended daily rhythm

- Morning: test one install flow, one messaging flow, and one posting flow on a real phone.
- Midday: review new bugs, response rates, and unread counters in admin/account surfaces.
- Evening: re-test anything fixed that day in both browser mode and installed-PWA mode.
